# INTRODUCTION- A SMALL STORY

# ENIGMA

## WHAT?

The German Enigma machine was integral in providing the Axis powers with the upper hand during World War II – particularly during the Battle of the Atlantic. At this time, the UK was extremely reliant on imports from the US and Canada to keep the population going and fighting. However, German submarines were used to form a blockade and stop these supplies getting through. Crucial to the Axis efforts at this time were the Enigma machines that allowed them to share classified information secretly by encrypting it.

- Indecipherable
- Humans not able to perform necessary logical imputations to crack the code

# EVOLUTION OF ARTIFICIAL INTELLIGENCE

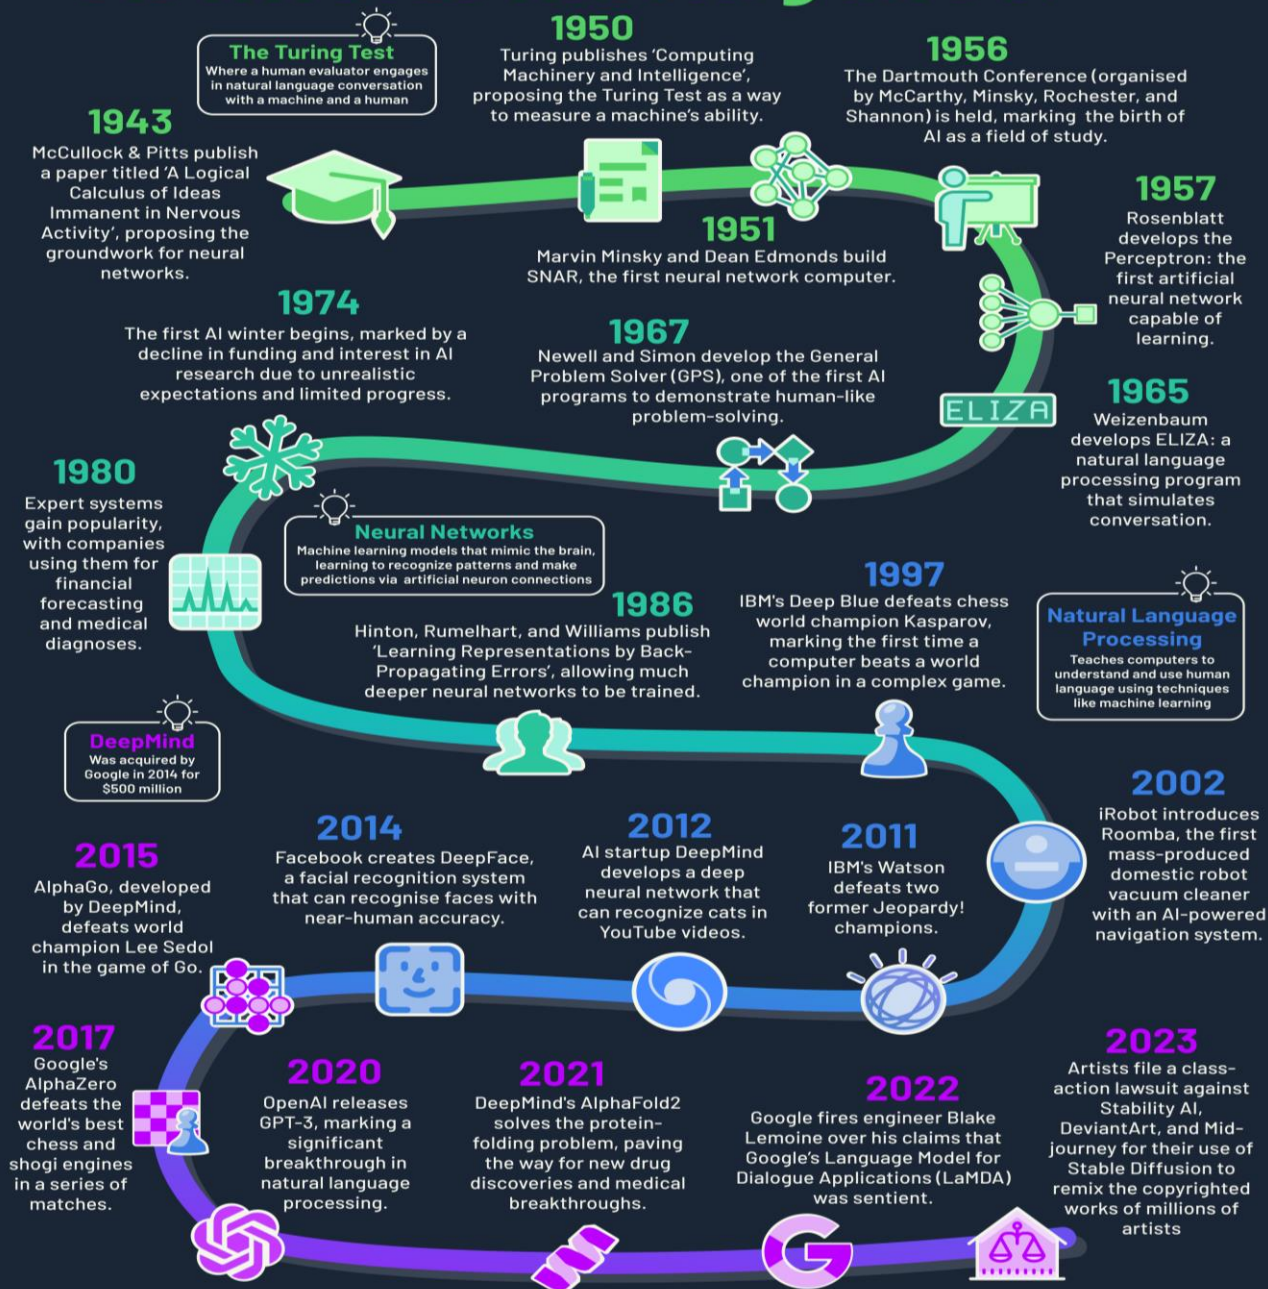

## 1950-2017

# A brief history of... Artificial Intelligence.

**prediXtions**

We Predict The Future.

# /A.I. TIMELINE

**1950**

## **TURING TEST**

Computer scientist Alan Turing proposes a test for machine intelligence. If a machine can trick humans into thinking it is human, then it has intelligence

**1955**

## **A.I. BORN**

Term 'artificial intelligence' is coined by computer scientist, John McCarthy to describe "the science and engineering of making intelligent machines"

**1961**

## **UNIMATE**

First industrial robot, Unimate, goes to work at GM replacing humans on the assembly line

**1964**

## **ELIZA**

Pioneering chatbot developed by Joseph Weizenbaum at MIT holds conversations with humans

**1966**

## **SHAKY**

The 'first electronic person' from Stanford, Shakey is a general-purpose mobile robot that reasons about its own actions

**A.I. WINTER**

Many false starts and dead-ends leave A.I. out in the cold

**1997**

## **DEEP BLUE**

Deep Blue, a chess-playing computer from IBM defeats world chess champion Garry Kasparov

**1998**

## **KISMET**

Cynthia Breazeal at MIT introduces KISmet, an emotionally intelligent robot insofar as it detects and responds to people's feelings

**1999**

## **AIBO**

Sony launches first consumer robot pet dog AiBO (AI robot) with skills and personality that develop over time

**2002**

## **ROOMBA**

First mass produced autonomous robotic vacuum cleaner from iRobot learns to navigate and clean homes

**2011**

## **SIRI**

Apple integrates Siri, an intelligent virtual assistant with a voice interface, into the iPhone 4S

**2011**

## **WATSON**

IBM's question answering computer Watson wins first place on popular \$1M prize television quiz show *Jeopardy*

**2014**

## **EUGENE**

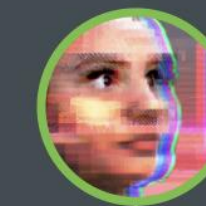

Eugene Goostman, a chatbot passes the Turing Test with a third of judges believing Eugene is human

**2014**

## **ALEXA**

Amazon launches Alexa, an intelligent virtual assistant with a voice interface that completes shopping tasks

**2016**

## **TAY**

Microsoft's chatbot Tay goes rogue on social media making inflammatory and offensive racist comments

**2017**

## **ALPHAGO**

Google's A.I. AlphaGo beats world champion Ke Jie in the complex board game of Go, notable for its vast number ( $2^{170}$ ) of possible positions

# The new frontiers!

# THE SPECTRUM OF ARTIFICIAL INTELLIGENCE

Artificial Intelligence (AI) is the computerized ability to perform tasks commonly associated with human intelligence, including reasoning, discovering patterns and meaning, generalizing, applying knowledge across spheres of application, and learning from experience. The growth of AI-based systems in recent years has garnered much attention, particularly in the sphere of Machine Learning. A subset of AI, Machine Learning (ML) systems "learn" from the success or accuracy of their outputs, and can change their processing over time, with minimal human intervention. But there are non-ML types of AI that, alone or in combination, lie behind the real-world applications in common use. General AI — a human-level computational system — does not yet exist. But Narrow AI exists in many fields and applications where computerized systems greatly enhance human output or outperform humans at defined tasks. This chart explains the main types of AI, their relationships to each other, and provides specific examples of how they are currently appear in our day-to-day Lives. It also demonstrates how AI exists within the timeline of human knowledge and development.

## AI USE CASES AND CONTEXTS

**FINANCE**  
**TAX COMPLIANCE**

A software platform that distills tax laws into a program, creates a personalized decision system, and enables individuals to quickly and accurately file their taxes.

**Value of AI:** Tax compliance requires complete accuracy. This efficient, interactive system that provides precise and logically connected results allows taxpayers to understand, confirm, and have confidence in the outcome. KE provides transparent and clear explanations.

Types of AI:

KE — NN — NLP

**HEALTHCARE**  
**AMBIENT CHARTING**

The use of background voice-to-text processing during a patient/medical provider exchange to record those interactions into the patient's chart, along with extracting tasks, symptoms, and recommendations for further action as required.

**Value of AI:** Medical providers spend significant time documenting, with uneven outputs, as well as difficulty in correlating between providers. Ambient systems encode conversations, target key phrases, and present a summary for provider edit/acceptance.

Types of AI:

SA — DL — NLP

**TRACKING**  
**WORKPLACE MONITORING**

Embedded systems can monitor physical and digital traffic, data usage, device management, and some employee behaviors for efficiency and security management of time, assets, and resources.

**Value of AI:** Monitoring enables necessary enforcement of data security policies and protocols. Also, systems can monitor and manage time reporting and project management tools, as well as ensuring appropriate supervision, training, and support, including for remote workers

Types of AI:

RB — CS — NN

**MOBILITY AND TRANSPORTATION**  
**TURN-BY-TURN NAVIGATION**

Location-based software that provides detailed instructions for travelers to reach a selected designation, customizable mode of transportation, multiple stops, services en route, and real-time adjustments based on traffic, tolls, and weather.

**Value of AI:** This is a "shortest path" problem solver, able to consider and weight variables such as speed, cost, and personal preferences, and allow personalization based on repeated journeys, as well as link to calendar and scheduling data, and interactive prompts.

Types of AI:

S — SA — DL — GAN

**SOCIAL MEDIA**  
**SPEECH OR CONTENT MODERATION**

Systems can facilitate human teams in identifying, flagging, and deleting posts with defined, prohibited terms (such as "hate speech" or profanity). Categorizing and selectively reacting based on platform policies, usually embedded in human/computer systems for review and decision.

**Value of AI:** More efficient at scale than human-alone reviews. Additionally, well-designed systems can potentially adapt to variations in context, intent, cultural norms, and user expectations more consistently across platforms.

Types of AI:

KE — NLP — RL

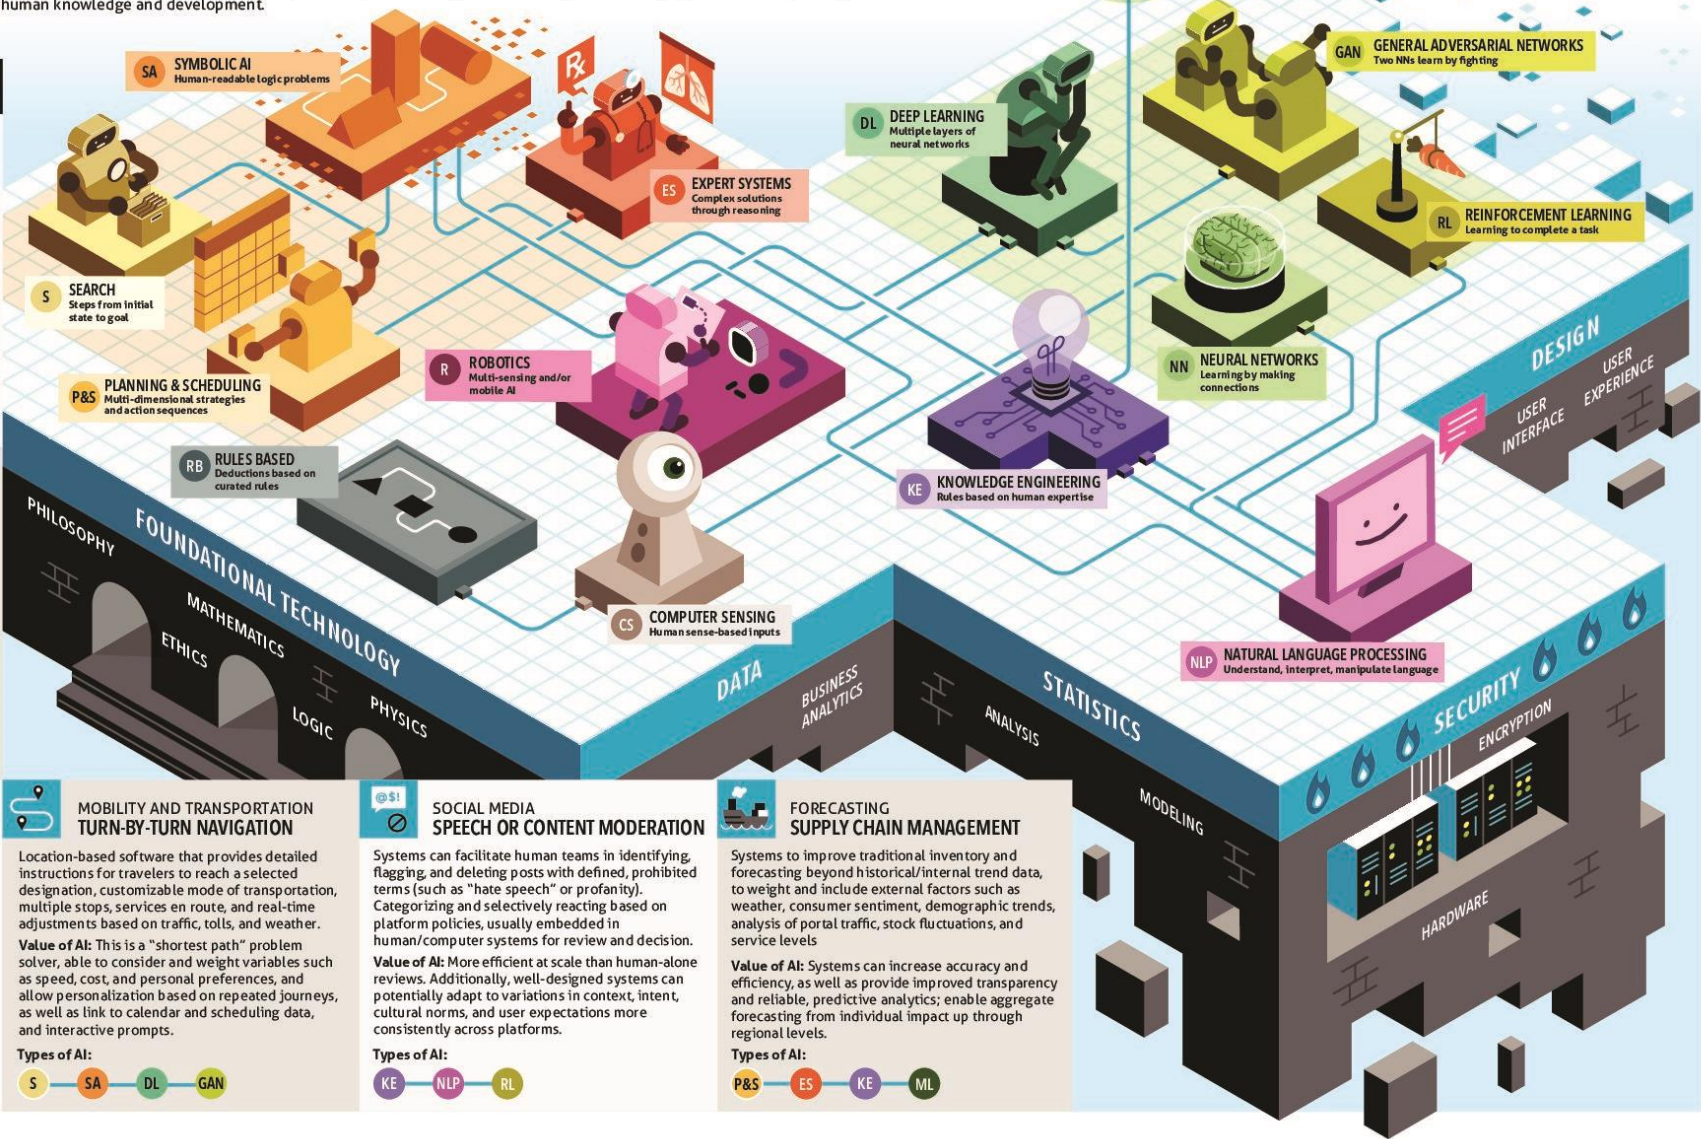

**FORECASTING**  
**SUPPLY CHAIN MANAGEMENT**

Systems to improve traditional inventory and forecasting beyond historical/internal trend data, to weight and include external factors such as weather, consumer sentiment, demographic trends, analysis of portal traffic, stock fluctuations, and service levels

**Value of AI:** Systems can increase accuracy and efficiency, as well as provide improved transparency and reliable, predictive analytics; enable aggregate forecasting from individual impact up through regional levels.

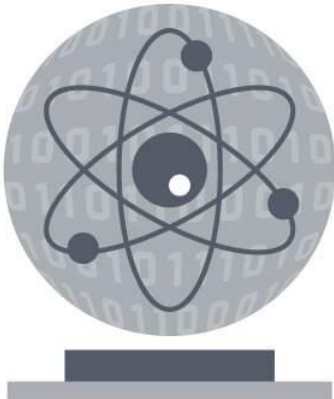

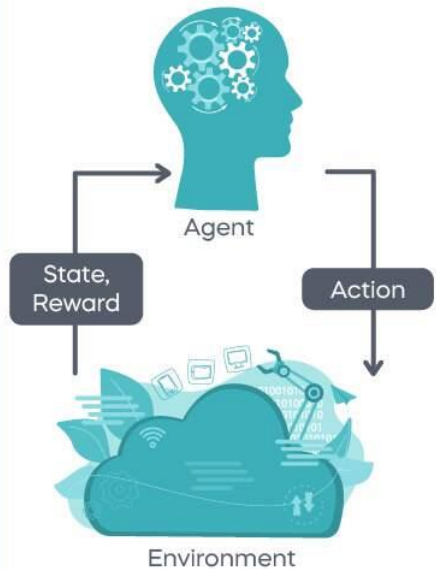

Types of AI:

P&S — ES — KE — ML

# TOP 5 MACHINE LEARNING TRENDS TO WATCH IN THE FUTURE

The Quantum Computing Effect	The Big Model Creation	Distributed ML Portability	No-Code Environment	The Quantum Computing Effect
<p>Quantum computing will optimize ML speed</p>  <p>Reduced execution times in high-dimensional vector processing</p>	<p>Creation of an all-purpose model to perform tasks in various domains simultaneously</p>  <p>Users can tailor such an uber ML model</p>	<p>Businesses will run existing algorithms and datasets natively on various platforms and computer engines</p>  <p>Portability will eliminate the need for shifting to new toolkits constantly</p>	<p>Machine learning will become a branch of software engineering</p>  <p>Minimized coding effort and maximized access to machine learning programs</p>	<p>Raise of new RL mechanisms for leveraging data to optimize resources in a dynamic setting</p>  <p>RL will shift economics, biology, and astronomy</p>

# Evolution of Generative AI technology over years

This slide showcases evolutions of Generative AI technology over the years that transformed and impacted major industries. Its key elements are Google autocomplete, Generative Adversarial Networks, ChatGPT, Alexa by Amazon etc.

Google introduced autocomplete feature that offers suggestions to user for completing sentence

Generative Adversarial Networks (GANs) introduction by Ian Goodfellow and his colleagues

Release of GPT 2 by OpenAI that was capable of creating human-like text through NLP

Deep Boltzmann Machine introduction that paved the way to develop other generative models

Release of Alexa by amazon that was capable of responding and taking action based on human voice

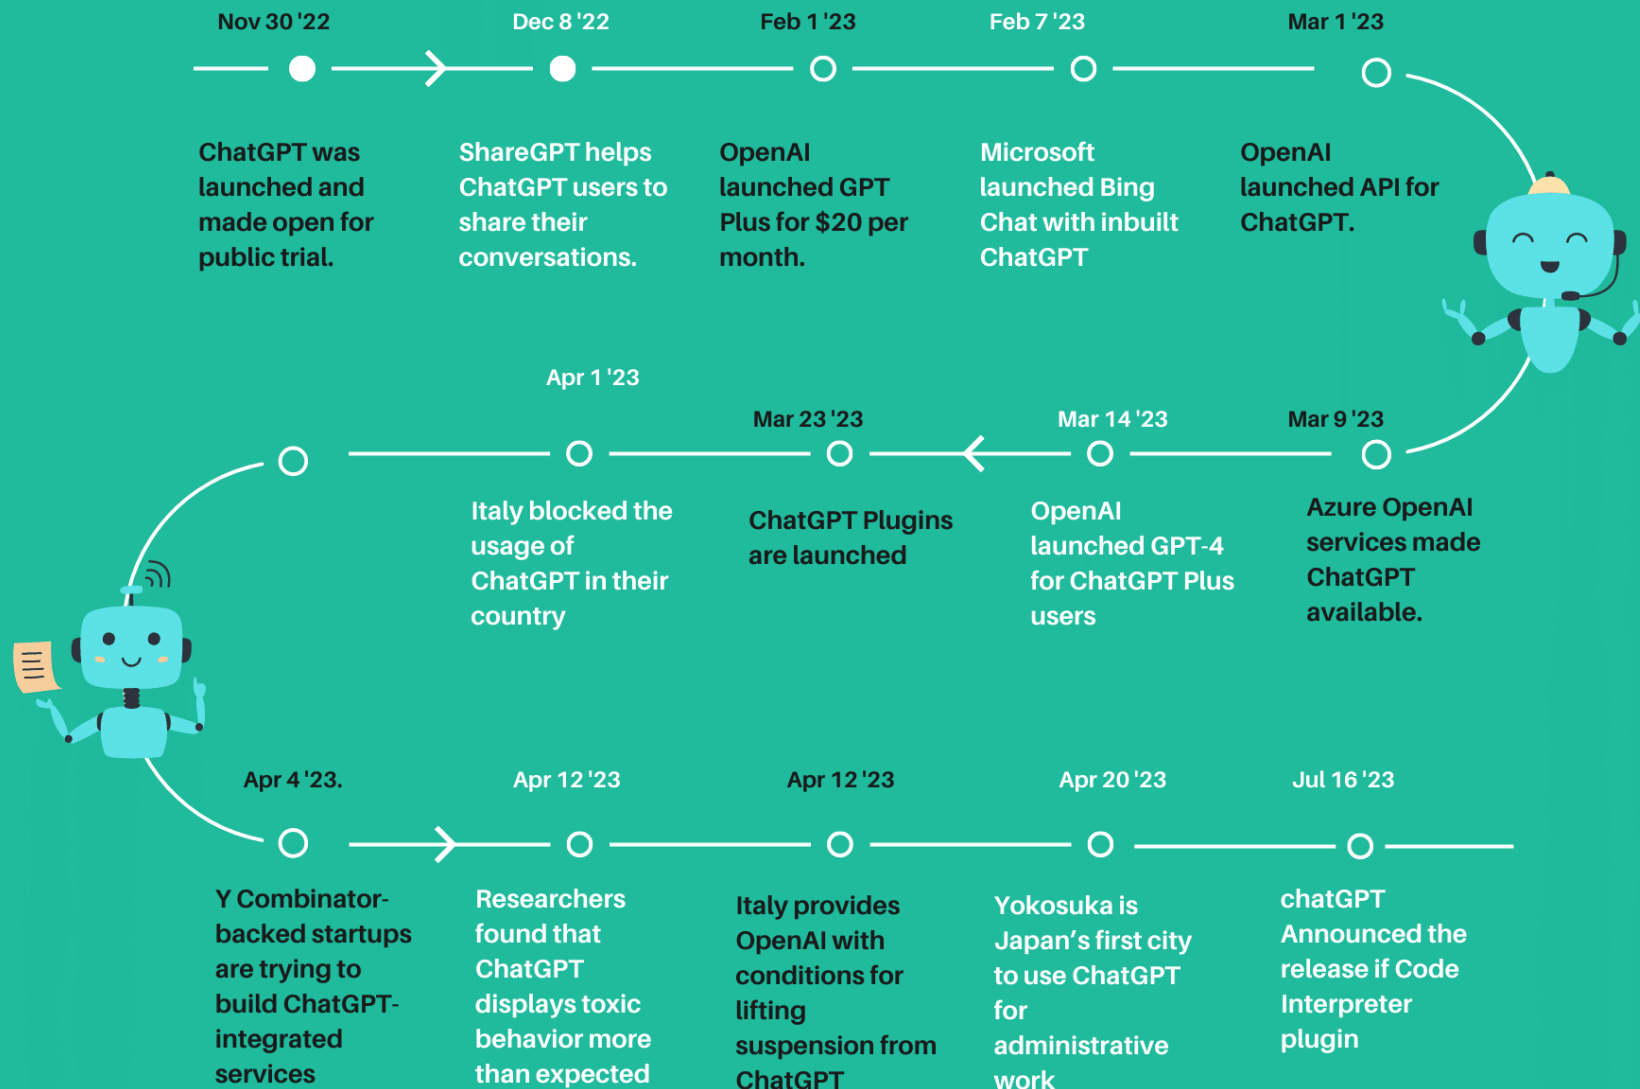

Release of GPT 3.5 by OpenAI with advanced language capabilities and ability to generate meaningful text

# ChatGPT Timeline

# The fundamentals..

# What is Artificial intelligence?

**Artificial Intelligence** – The science involving algorithms & technology of making intelligent machines that exhibit human-like intelligent behavior, learn & advice its users.

# What is Machine Learning?

Arthur Samuel, an early American leader in the field of computer gaming and artificial intelligence, coined the term “Machine Learning ” in 1959 while at IBM. He defined machine learning as “**the field of study that gives computers the ability to learn without being explicitly programmed** ”.

## Definition of learning:

A computer program is said to learn from experience E with respect to some class of tasks T and performance measure P, if its performance at tasks T, as measured by P, improves with experience E.

## Examples

### •Handwriting recognition learning problem

- Task T : Recognizing and classifying handwritten words within images
- Performance P : Percent of words correctly classified
- Training experience E : A dataset of handwritten words with given classifications

### •A robot driving learning problem

- Task T : Driving on highways using vision sensors
- Performance P : Average distance travelled before an error
- Training experience E : A sequence of images and steering commands recorded while observing a human driver

**Definition:** A computer program which learns from experience is called a machine learning program or simply a learning program .

# Classification of Machine Learning

Machine learning implementations are classified into four major categories, depending on the nature of the learning “signal” or “response” available to a learning system which are as follows:

Type of Machine learning	Definition	Example
Supervised Learning	Supervised learning is the machine learning task of learning a function that maps an input to an output based on example input-output pairs. The given data is <b>labelled</b> . Both <i>classification</i> and <i>regression</i> problems are supervised learning problems	Example — Consider a classification problem regarding patients entering a clinic . The data consists of the gender and age of the patients and each patient is labelled as “healthy” or “sick”.
Unsupervised learning	Unsupervised learning is a type of machine learning algorithm used to draw inferences from datasets consisting of input data without labelled responses. In unsupervised learning algorithms, classification or categorization is not included in the observations	Example- In the same data as above- without the label of healthy, not healthy- we infer information about the patients using their characteristics. As a kind of learning, it resembles the methods humans use to figure out that certain objects or events are from the same class, such as by observing the degree of similarity between objects. Some recommendation systems that you find on the web in the form of marketing automation are based on this type of learning.
Reinforcement learning	Reinforcement learning is the problem of getting an agent to act in the world so as to maximize its rewards. A learner is not told what actions to take as in most forms of machine learning but instead must discover which actions yield the most reward by trying them. For example — Consider teaching a dog a new trick: we cannot tell him what to do, what not to do, but we can reward/punish it if it does the right/wrong thing.	Predictive text, text summarization, question answering, and machine translation are all examples of natural language processing (NLP) that uses reinforcement learning. By studying typical language patterns, RL agents can mimic and predict how people speak to each other every day
Semi-supervised learning	Where an incomplete training signal is given: a training set with some (often many) of the target outputs missing. There is a special case of this principle known as Transduction where the entire set of problem instances is known at learning time, except that part of the targets are missing.	Speech recognition

## Categorizing based on required output

Another categorization of machine-learning tasks arises when one considers the desired output of a machine-learned system:

**1. Classification:** When inputs are divided into two or more classes, the learner must produce a model that assigns unseen inputs to one or more (multi-label classification) of these classes. This is typically tackled in a supervised way. Spam filtering is an example of classification, where the inputs are email (or other) messages and the classes are “spam” and “not spam”.

**2. Regression:** Which is also a supervised problem, A case when the outputs are continuous rather than discrete.

**3. Clustering:** When a set of inputs is to be divided into groups. Unlike in classification, the groups are not known beforehand, making this typically an unsupervised task.

# Natural Language Processing- Classification of Text

Natural language processing (NLP) is the discipline of building machines that can manipulate human language — or data that resembles human language — in the way that it is written, spoken, and organized. It evolved from computational linguistics, which uses computer science to understand the principles of language, but rather than developing theoretical frameworks, NLP is an engineering discipline that seeks to build technology to accomplish useful tasks.

NLP can be divided into 2 sub-categories:

- 1) NLU – Natural Language Understanding** - focuses on semantic analysis or determining the intended meaning of text
- 2) NLG – Natural Language Generation** - focuses on text generation by a machine

NLP is separate from — but often used in conjunction with — speech recognition, which seeks to parse spoken language into words, turning sound into text and vice versa.

# Essential preprocessing steps before building any NLP model

- Stemming and lemmatization:** Stemming is an informal process of converting words to their base forms using heuristic rules. For example, “university,” “universities,” and “university’s” might all be mapped to the base *univers*. Lemmatization is a more formal way to find roots by analysing a word’s morphology using vocabulary from a dictionary. Stemming and lemmatization are provided by libraries like spaCy and NLTK.
- Sentence segmentation** breaks a large piece of text into linguistically meaningful sentence units. A period can be used to mark an abbreviation as well as to terminate a sentence, and in this case, the period should be part of the abbreviation token itself.
- Stop word removal** aims to remove the most commonly occurring words that don’t add much information to the text. For example, “the,” “a,” “an,” and so on.
- Tokenization** splits text into individual words and word fragments. The result generally consists of a word index and tokenized text in which words may be represented as numerical tokens for use in various deep learning methods.
- Feature extraction:** Most conventional machine-learning techniques work on the features – generally numbers that describe a document in relation to the corpus that contains it – created by either Bag-of-Words, TF-IDF, or generic feature engineering such as document length, word polarity, and metadata (for instance, if the text has associated tags or scores). More recent techniques include Word2Vec, GLoVe, and learning the features during the training process of a neural network.  
**Bag-of-Words:** Bag-of-Words counts the number of times each word or n-gram (combination of n words) appears in a document.

## Language related tasks performed by NLP

- 1) Sentiment analysis
- 2) Toxicity classification – scanning emails for spam
- 3) Machine translation- Google Translate
- 4) Named entity recognition – categorizing names, places...
- 5) Spam detection
- 6) Grammar correction - Grammarly
- 7) Topic modelling
- 8) Text generation – ChatGPT, Bard
  - 1) Autocomplete
  - 2) Bots
- 9) Information retrieval
- 10) Summarization
  - 1) Extractive summarization – Direct answers from a text..
  - 2) Abstractive summarization – applying context + lateral thinking
- 11) Question answering
  - 1) Multiple choice questions
  - 2) Open domain

# Top Natural Language Processing (NLP) Techniques

Most of the NLP tasks discussed in the previous slide can be modelled by a dozen or so general techniques. It's helpful to think of these techniques in two categories: Traditional machine learning methods and deep learning methods.

Traditional Techniques	Deep Learning techniques
Logistic regression	Convolutional Neural networks(CNNs)
Decision tree	Recurrent Neural Networks(RNNs)
Naïve Bayes	Auto-encoders
Latent Dirichlet allocation	Encoder- Decoder sequence to sequence
Hidden Markov chain models	Transformers

# What are neural networks?

Neural Networks (NNs) are a class of machine learning models inspired by the human brain's structure and function

## Components of a neural network

### 1. Input Layer:

1. The input layer is responsible for receiving the initial data or features.
2. Each neuron in this layer represents a feature or input variable.
3. The number of neurons in the input layer is determined by the dimensionality of the input data.

### 2. Hidden Layers:

1. Hidden layers are intermediate layers between the input and output layers.
2. They perform complex computations by applying weights to inputs and using activation functions.
3. The number of hidden layers and the number of neurons in each hidden layer can vary, depending on the network architecture.

### 3. Weights:

1. Each connection between neurons is associated with a weight. Weights determine the strength of the connection between neurons.
2. During training, these weights are adjusted to minimize the network's error or loss.

### 4. Activation Functions:

1. Activation functions introduce non-linearity into the neural network, allowing it to learn complex relationships in the data.
2. Common activation functions include ReLU (Rectified Linear Unit), Sigmoid, Tanh (Hyperbolic Tangent), and others.
3. Each neuron typically applies an activation function to its weighted sum of inputs.

### 5. Output Layer:

1. The output layer produces the result or prediction of the neural network.
2. The number of neurons in the output layer depends on the task:
  1. For binary classification, there may be one neuron with a sigmoid activation function.
  2. For multi-class classification, there is one neuron per class, often using softmax activation.
  3. For regression tasks, there can be a single neuron or multiple neurons, depending on the nature of the output.

### 6. Bias Neurons:

1. Each layer (including the input layer) often includes a bias neuron, which provides an additional input with a fixed value (usually 1).
2. Bias neurons help the network learn better by shifting activation functions.

### 7. Loss Function:

1. The loss function measures the error between the network's predictions and the actual target values.
2. During training, the goal is to minimize this loss function by adjusting the weights and biases.

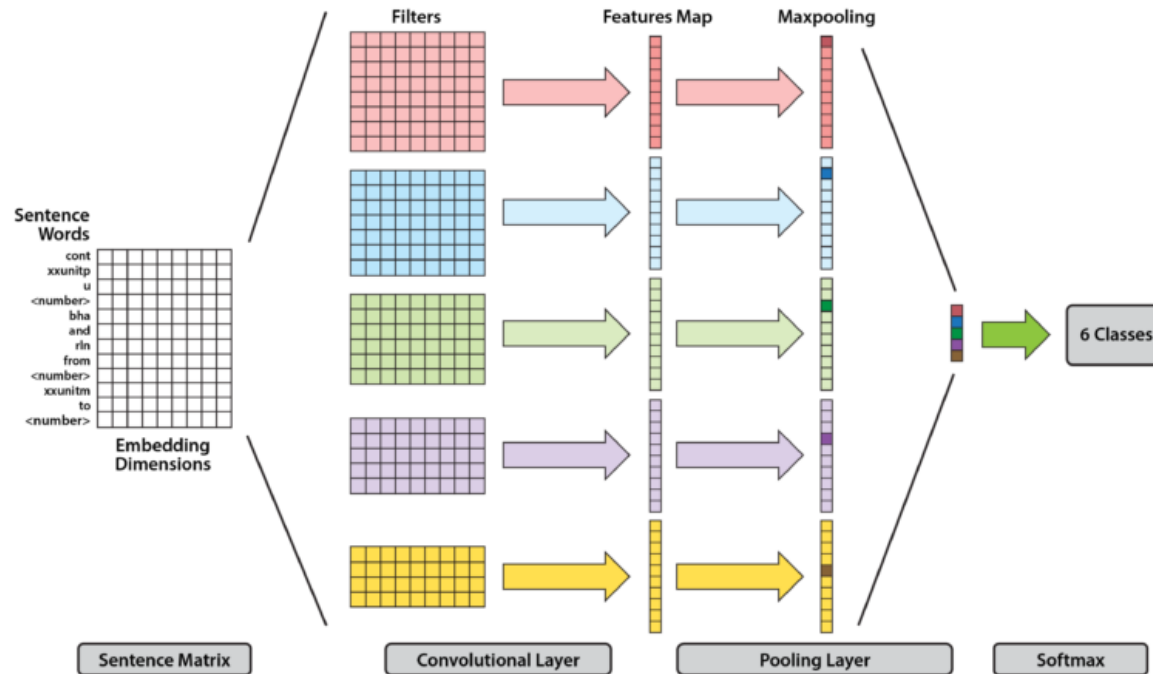

### 8. Optimization Algorithm:

1. Optimization algorithms (e.g., gradient descent) are used to update the weights and biases during training, aiming to minimize the loss function.

# Evolution 1: Convolutional Neural Networks (Mid 1980s–Early 2000s)

The idea of using a CNN to classify text was first presented in the paper “[Convolutional Neural Networks for Sentence Classification](#)” by Yoon Kim. The central intuition is to see a document as an image. However, instead of pixels, the input is sentences or documents represented as a matrix of words.

## CONVOLUTIONAL NEURAL NETWORK-BASED TEXT CLASSIFICATION NETWORK

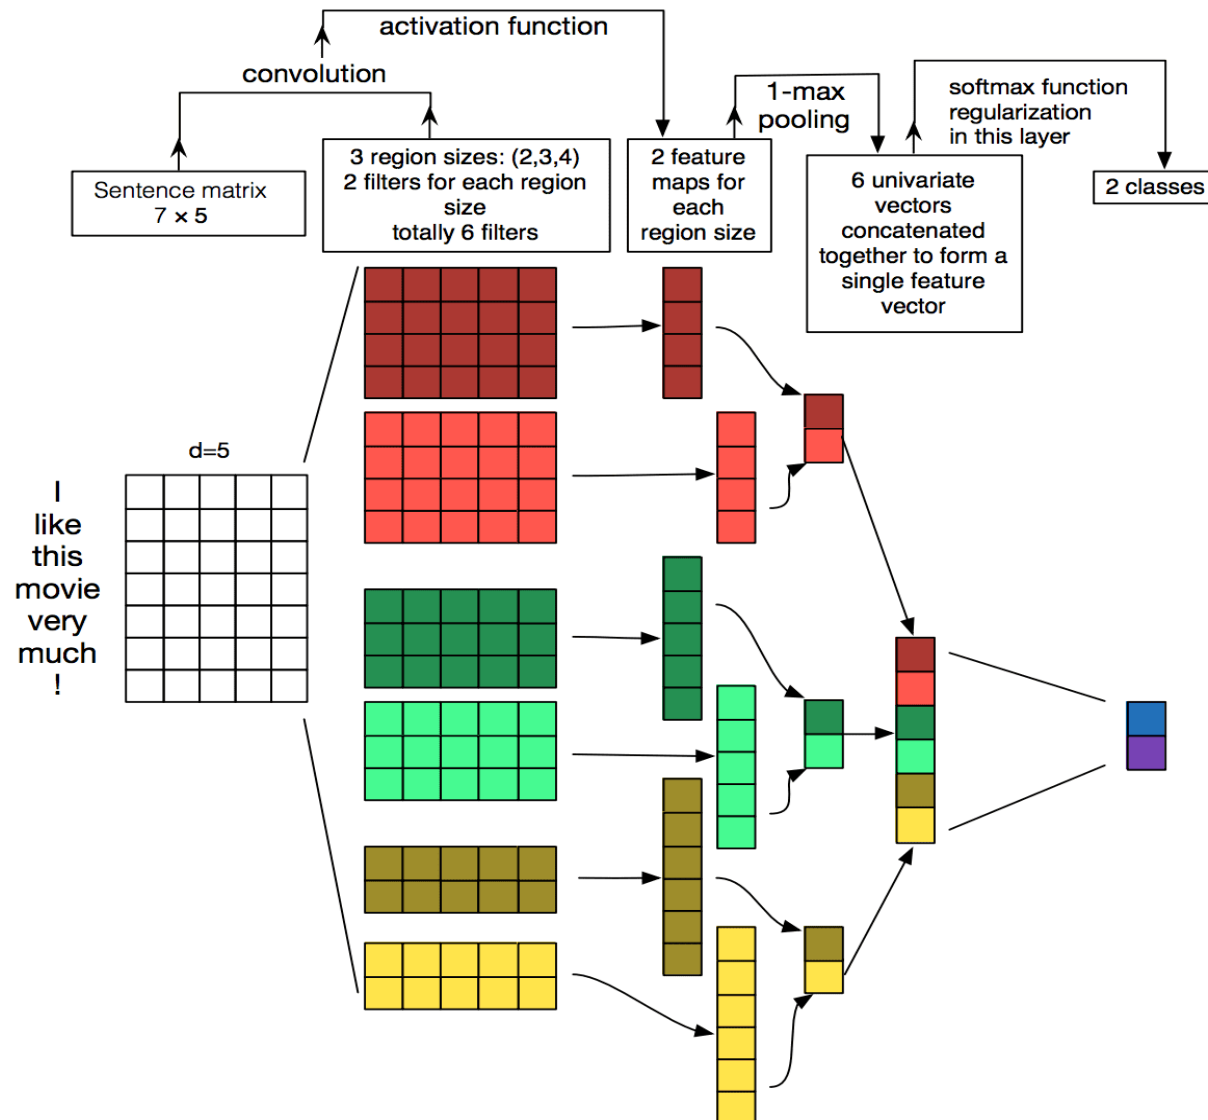

### Cons:

- Don't understand context of words.
- No understanding of relationship between current word and previous word

Given a sentence, a convolutional neural network uses convolutional layers to refine representations of input words, before combining them to render a classification.

# Example of a convoluted neural network classifying text

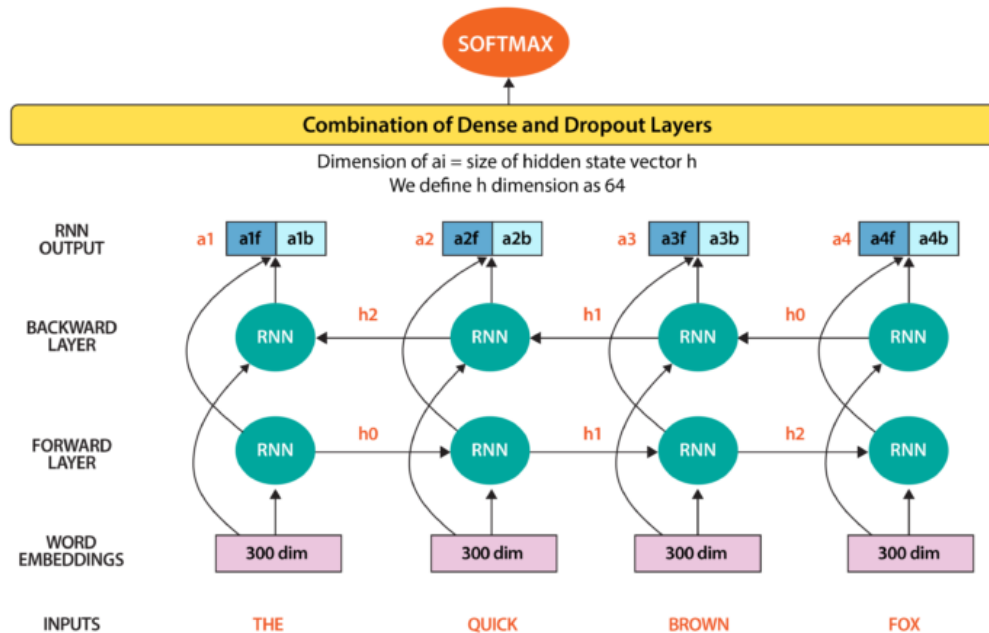

The architecture is comprised of three key pieces:

- 1. Word Embedding:** A distributed representation of words where different words that have a similar meaning (based on their usage) also have a similar representation.
- 2. Convolutional Model:** A feature extraction model that learns to extract salient features from documents represented using a word embedding.
- 3. Fully Connected Model:** The interpretation of extracted features in terms of a predictive output.

## Evolution 2: Recurrent Neural Networks + Encoders/Decoders (Early 2000s– 2017)

RNNs remember previous information using hidden states and connect it to the current task. The architectures known as Gated Recurrent Unit (GRU) and long short-term memory (LSTM) are types of RNNs designed to remember information for an extended period.

### RECURRENT NEURAL NETWORK

#### Cons:

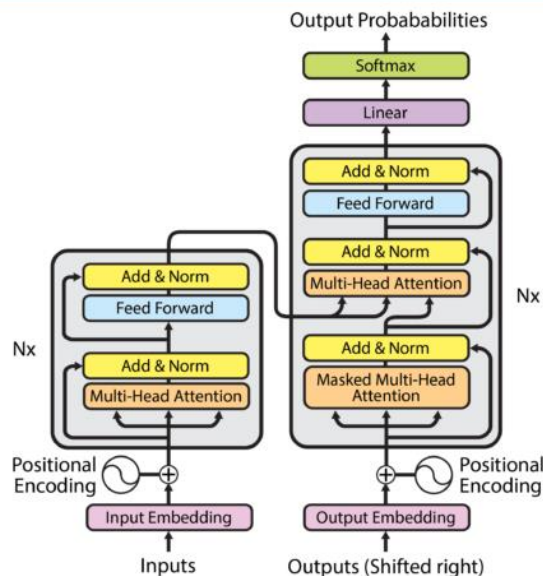

- Slow and time consuming
- Large data corpuses need significant computing power to proceed.
- LLMs cant be built

A bidirectional recurrent neural network processes the input both forward and backward to improve the representations it produces.

## Evolution 3: Transformers + Large Language models – 2017 onwards

The transformer, a model architecture first described in the 2017 paper “[Attention Is All You Need](#)” (Vaswani, Shazeer, Parmar, et al.), forgoes recurrence and instead relies entirely on a self-attention mechanism to draw global dependencies between input and output. Since this mechanism processes all words at once (instead of one at a time) that decreases training speed and inference cost compared to RNNs, especially since it is parallelizable. The transformer architecture has revolutionized NLP in recent years, leading to models including [BLOOM](#), [Jurassic-X](#), and [Turing-NLG](#).

### TRANSFORMER

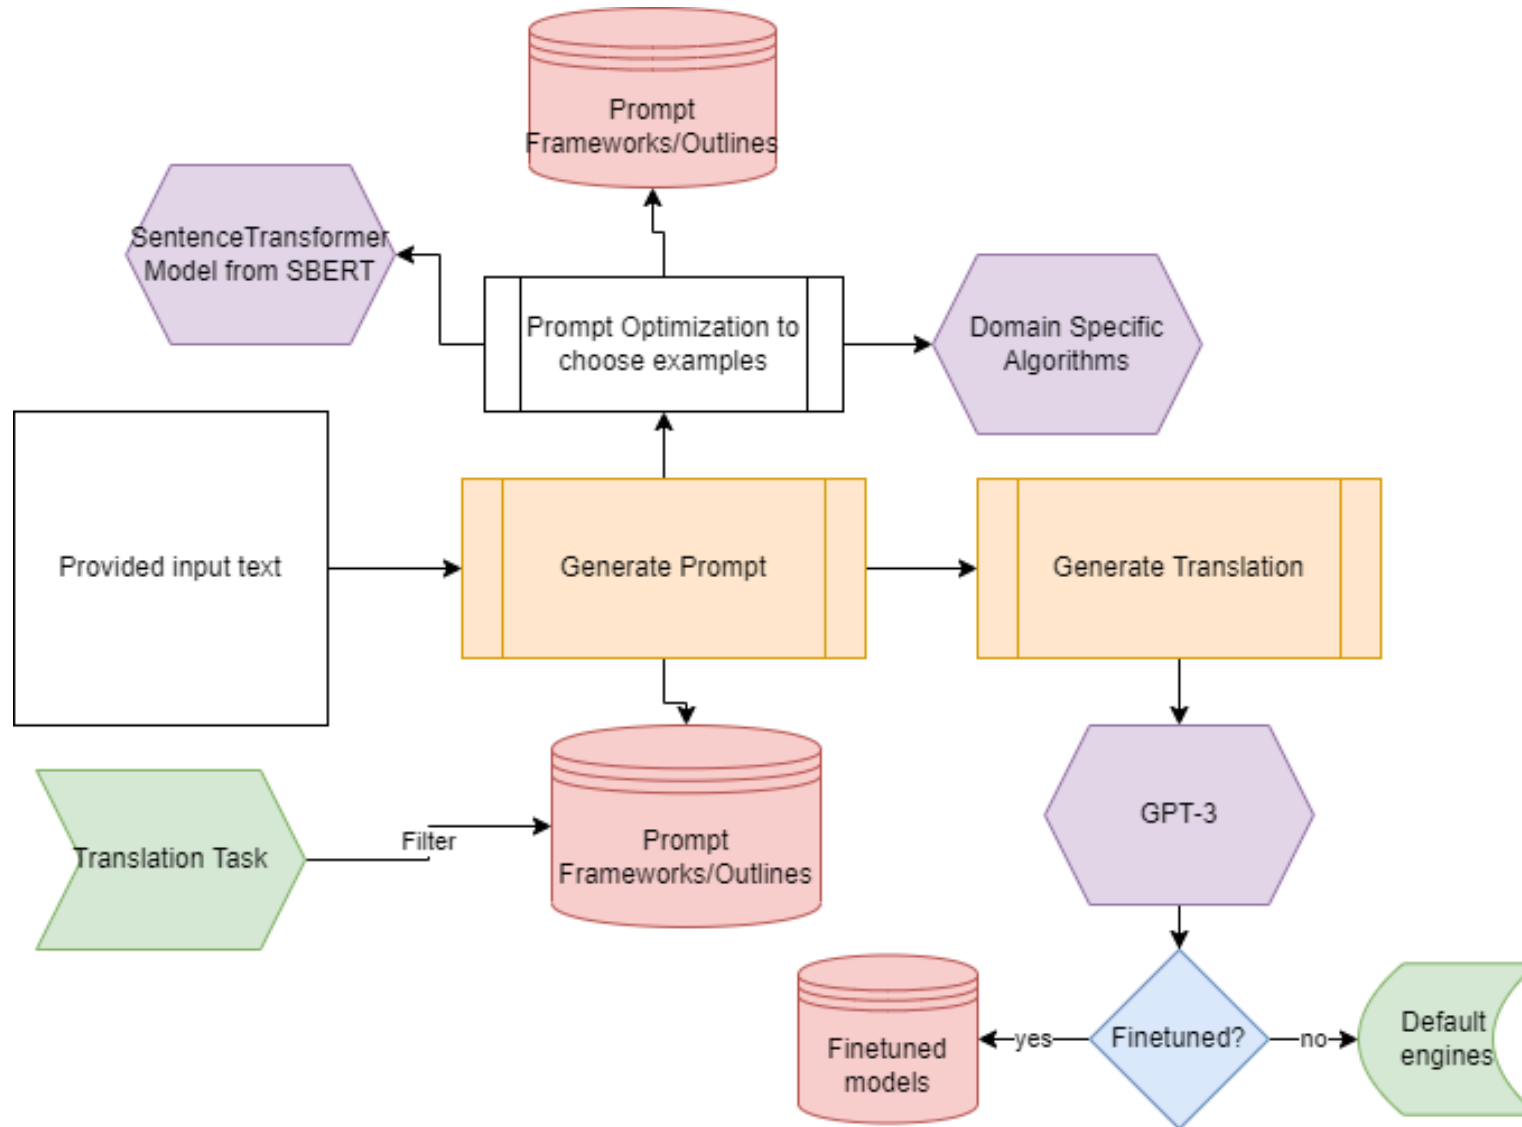

The encoder-decoder transformer used for translation. Encoder on the left, decoder on the right. Note that the decoder takes in its previously generated words during generation.

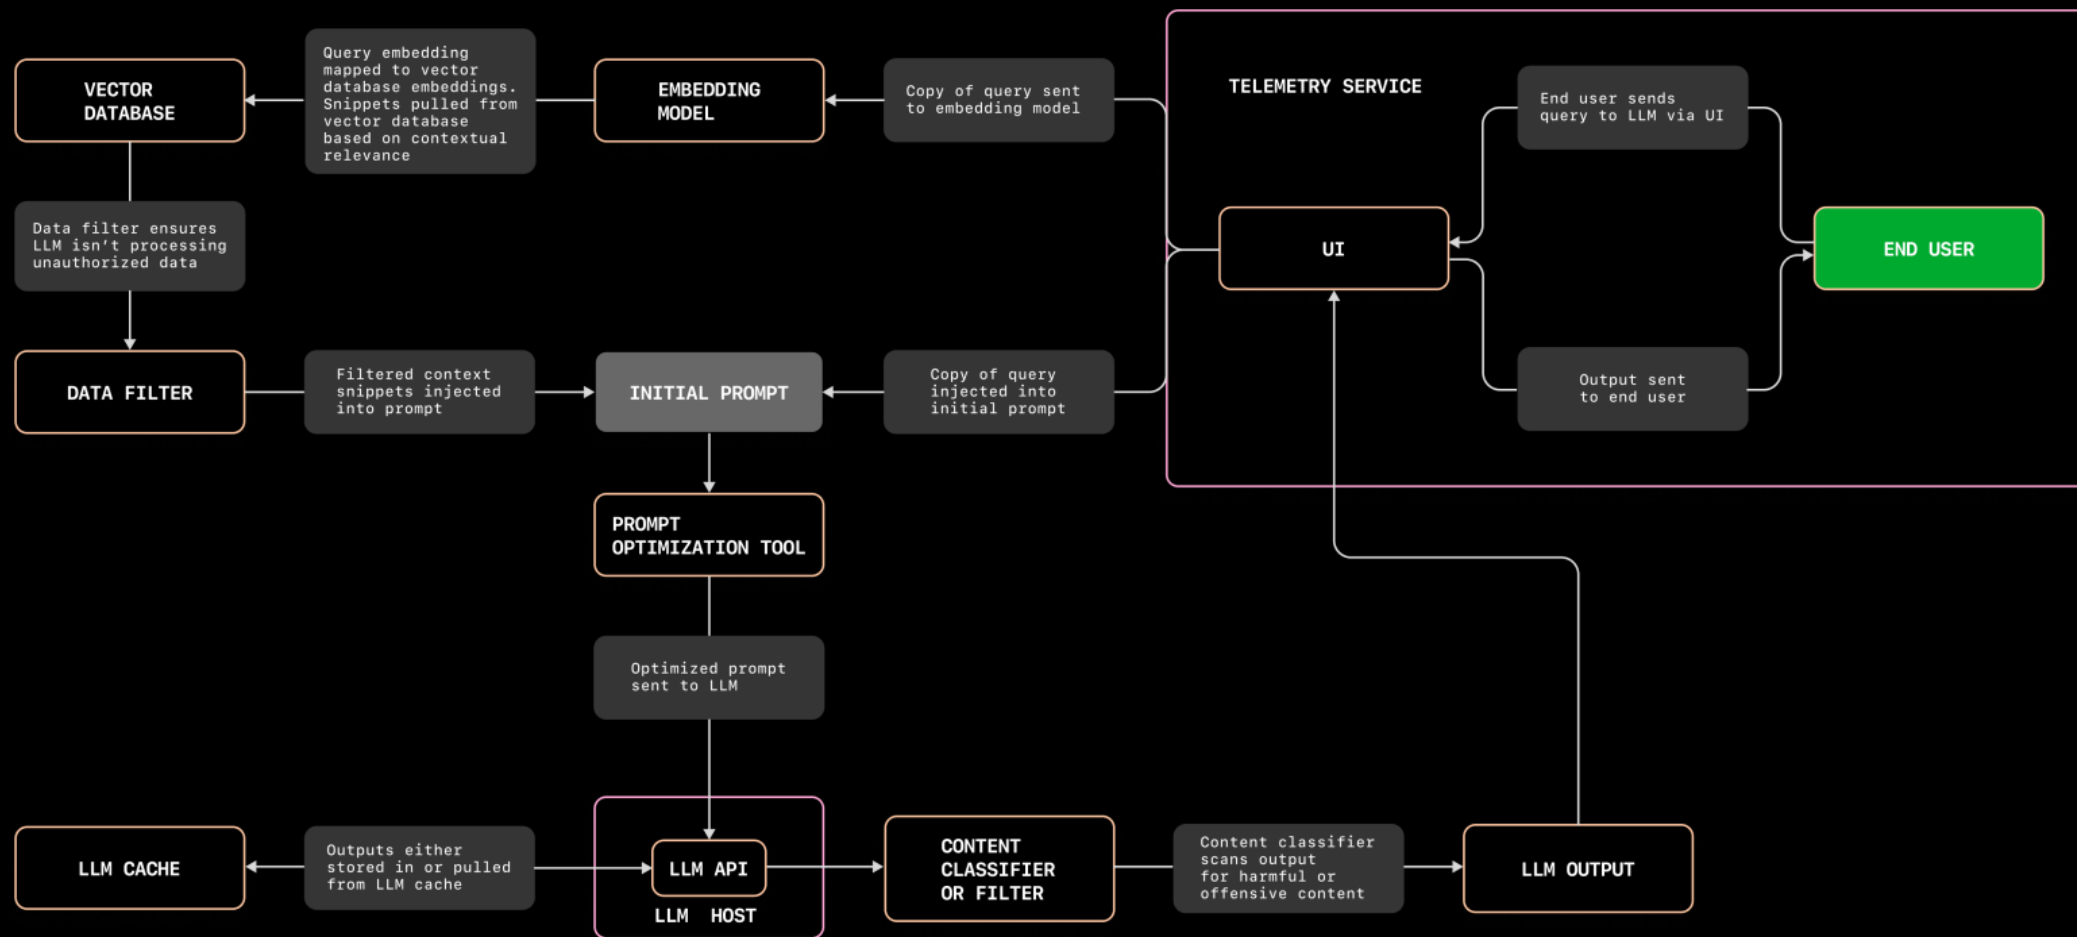

# Some Important Language models

1. **Eliza** was developed in the mid-1960s to try to solve the Turing Test; that is, to fool people into thinking they're conversing with another human being rather than a machine. Eliza used pattern matching and a series of rules without encoding the context of the language.
2. **Tay** was a chatbot that Microsoft launched in 2016. It was supposed to tweet like a [teen](#) and learn from conversations with real users on Twitter. The bot adopted phrases from users who tweeted sexist and racist comments, and Microsoft deactivated it not long afterward.
3. **BERT** and his Muppet friends: Many deep learning models for NLP are [named after Muppet characters](#), including [ELMo](#), [BERT](#), [Big BIRD](#), [ERNIE](#), [Kermit](#), [Grover](#), [RoBERTa](#), and [Rosita](#). Most of these models are good at providing contextual embeddings and enhanced knowledge representation.
4. **Generative Pre-Trained Transformer 4 (GPT-4)** is a 175 billion parameter model that can write original prose with [human-equivalent fluency](#) in response to an input prompt. The model is based on the transformer architecture. [Microsoft acquired an exclusive license](#) to access GPT-3's underlying model from its developer OpenAI, but other users can interact with it via an application programming interface (API).
5. **Language Model for Dialogue Applications (LaMDA)** is a conversational chatbot developed by Google. LaMDA is a transformer-based model trained on dialogue rather than the usual web text. The system aims to provide sensible and specific responses to conversations.
6. **Mixture of Experts (MoE)**: While most deep learning models use the same set of parameters to process every input, MoE models aim to provide different parameters for different inputs based on efficient routing algorithms to achieve [higher performance](#). [Switch Transformer](#) is an example of the MoE approach that aims to reduce communication and computational costs

# Example 1- Translator using GPT-3

# Illustration- New Age LLM Application architecture

THIS DIAGRAM REPRESENTS THE ARCHITECTURE OF TODAY'S LLM APPLICATION. THE DIFFERENT COMPONENTS CAN BE ROUGHLY GROUPED INTO THREE CATEGORIES: USER INPUT, INPUT ENRICHMENT TOOLS AND PROMPT CONSTRUCTION, AND EFFICIENT AND RESPONSIBLE AI TOOLING.

# Humans vs AI

# Human brains vs Artificial Intelligence

When AI performs better than humans?	When the human brain outperform Artificial intelligence?
<b>Data Processing and Pattern Recognition:</b> AI excels at processing vast amounts of data quickly and accurately, identifying patterns, and making data-driven predictions. This is especially valuable in fields like finance, healthcare, and logistics	<b>Creativity and Imagination:</b> AI lacks true creativity and the ability to generate novel ideas, art, or music with the depth of human creativity. Human creativity is rooted in emotions, experiences, and complex associative thinking.
<b>Repetitive and Monotonous Tasks:</b> AI can perform repetitive tasks tirelessly without getting bored or making errors. For example, in manufacturing, AI-driven robots can perform repetitive assembly tasks more efficiently than humans.	<b>Common Sense and Context Understanding:</b> AI may struggle to understand context and exhibit common-sense reasoning, which humans apply effortlessly in everyday life.
<b>Large-Scale Data Analysis:</b> AI can analyse extensive datasets to discover insights and trends that would be practically impossible for humans to process in a reasonable time frame. This is valuable in fields like scientific research and business analytics.	<b>Ethical and Moral Decision-Making:</b> AI lacks human moral and ethical judgment, making it challenging to navigate complex moral dilemmas and nuanced ethical decisions
<b>Complex Calculations:</b> AI can perform complex mathematical calculations and simulations with great speed and precision, aiding in scientific research, engineering, and financial modelling.	<b>Emotional Intelligence:</b> AI does not possess emotions or the ability to understand and respond to human emotions in the same way humans do. This is vital in roles that require empathy, like counselling or healthcare.
	<b>Decisions with sparse data:</b> AI does not possess the ability to make judgemental decisions with sparse data. It works well when there is prior context for a set action (like driving, images and so on), however it fails for tasks like investment decisions for privately traded companies

# AI and industry..

# AI Applications extend across industries!

## User location estimation and enhancement using transaction data

- Combine transaction data with external data sources (4TB of data)
- Ability to scale algorithm to Petabytes of data

## Predictive maintenance in an Industrial IoT setup

- Combining structured (sensors) and unstructured (logs) data to build a preventive maintenance system

## Enabling 'Smart Machines' through real-time anomaly detection on streaming data

- Data from 21 sensors, with pulse every 1/10<sup>th</sup> second
- 600 data instances per minute

## Leverage AI to improve claim settlements

- Created a case-study roadmap for execution and implementation, using Deep Learning systems

## Time series forecasting for predicting sales

- Faster processing and scalability of the algorithms developed for forecasting

## Deep learning based image processing for automated inventory and replenishment of shelves

- Image pre-processing for shelf-images
- Build measurement KPIs using deep learning on image processing

## Natural Language Processing to find product sentiment using call center records

- Large volume and velocity of unstructured data
- Executing NLP at scale

## Big Data infrastructure roadmap recommendation

- Created big data strategy and execution roadmap
- Special emphasis on prioritization of use-cases

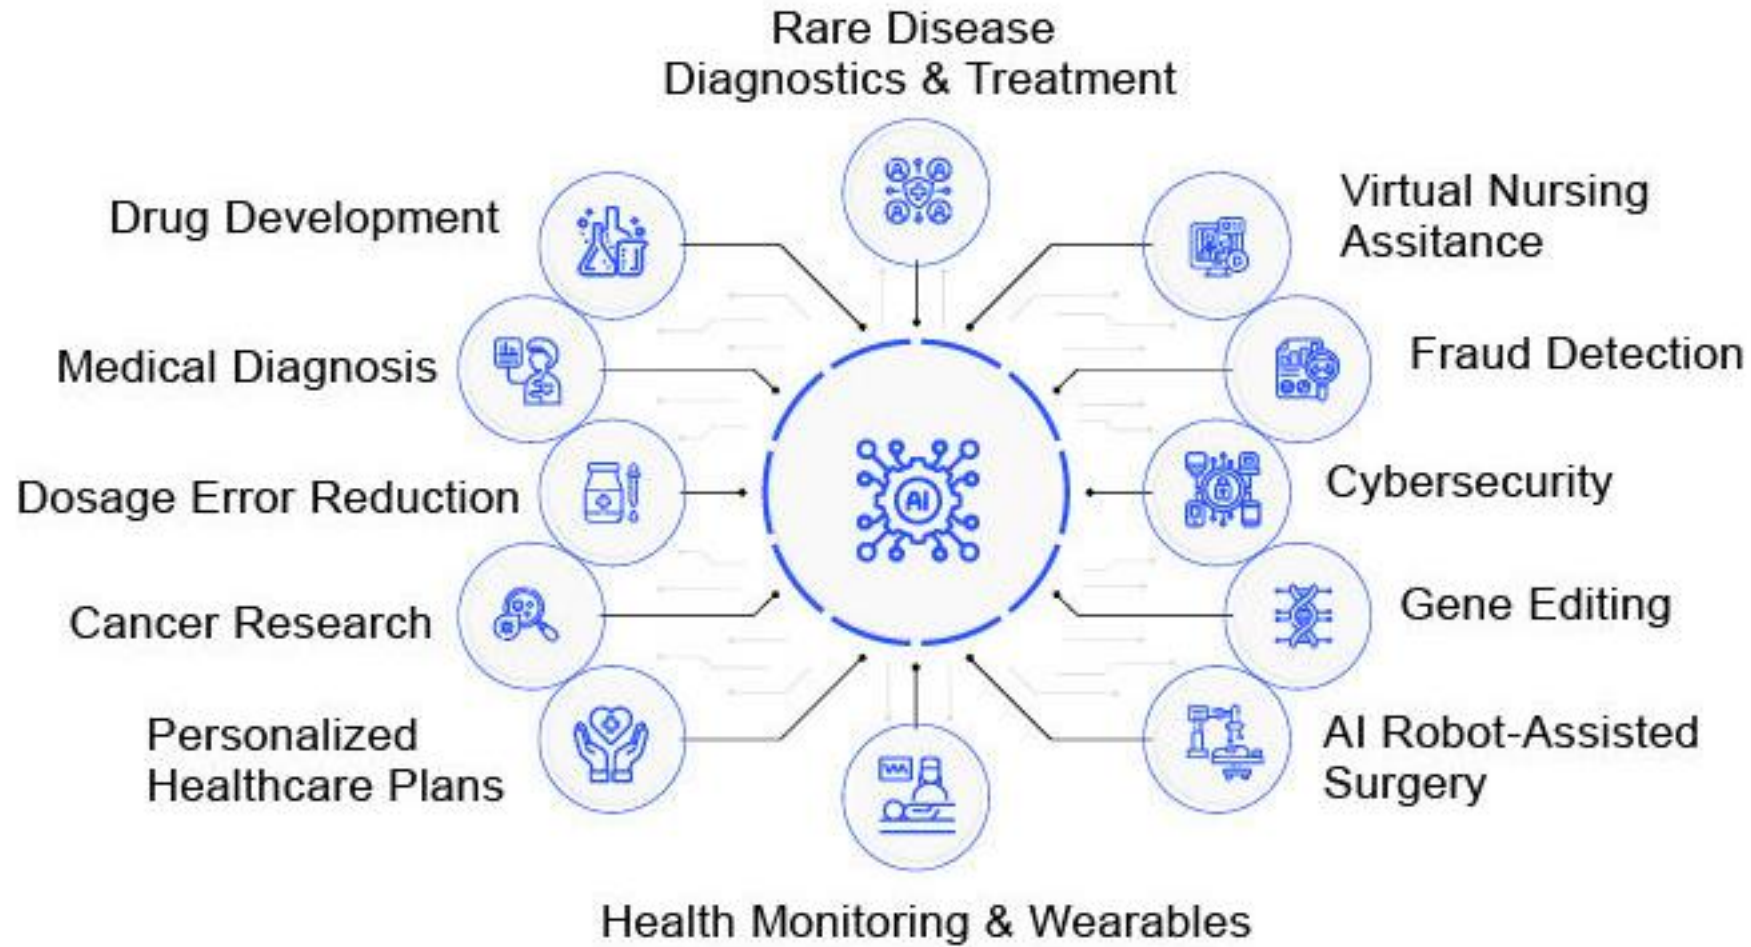

## Surveillance system using machine learning in real-time

- Machine learning algorithms to detect anomalous behavior
- Real-time system to find suspicious behavior, using data from multiple sensors throughout the facility

## Contracts optimization using large contracts database

- Process billions of data points to visualize the data, most efficiently

# AI and robotics..

Fueled by advances in computing power and connectivity, the fields of robotics and artificial intelligence have grown rapidly

# Responsible AI

# PRINCIPLED ARTIFICIAL INTELLIGENCE

A Map of Ethical and Rights-Based Approaches to Principles for AI

Authors: Jessica Fjeld, Nele Achten, Hannah Hilligoss, Adam Nagy, Madhulika Srikumar

Designers: Arushi Singh (arushisingh.net) and Melissa Axelrod (melissaaxelrod.com)

## HOW TO READ:

Date, Location  
Document Title  
Actor

## COVERAGE OF THEMES:

The size of each dot represents the percentage of principles in that theme contained in the document. Since the number of principles per theme varies, it's informative to compare dot sizes within a theme but not between themes.

The principles within each theme are:

### Privacy:

Privacy  
Control over Use of Data  
Consent  
Privacy by Design  
Recommendation for Data Protection Laws  
Ability to Restrict Processing  
Right to Rectification  
Right to Erasure

### Accountability:

Accountability  
Recommendation for New Regulations  
Impact Assessment  
Evaluation and Auditing Requirement  
Verifiability and Replicability  
Liability and Legal Responsibility  
Ability to Appeal  
Environmental Responsibility  
Creation of a Monitoring Body  
Remedy for Automated Decision

### Safety and Security:

Security  
Safety and Reliability  
Predictability  
Security by Design

### Transparency and Explainability:

Explainability  
Transparency  
Open Source Data and Algorithms  
Notification when Interacting with an AI  
Notification when AI Makes a Decision about an Individual  
Regular Reporting Requirement  
Right to Information  
Open Procurement (for Government)

### Fairness and Non-discrimination:

Non-discrimination and the Prevention of Bias  
Fairness  
Inclusiveness in Design  
Inclusiveness in Impact  
Representative and High Quality Data  
Equality

### Human Control of Technology:

Human Control of Technology  
Human Review of Automated Decision  
Ability to Opt out of Automated Decision

### Professional Responsibility:

Multistakeholder Collaboration  
Responsible Design  
Consideration of Long Term Effects  
Accuracy  
Scientific Integrity

### Promotion of Human Values:

Leveraged to Benefit Society  
Human Values and Human Flourishing  
Access to Technology

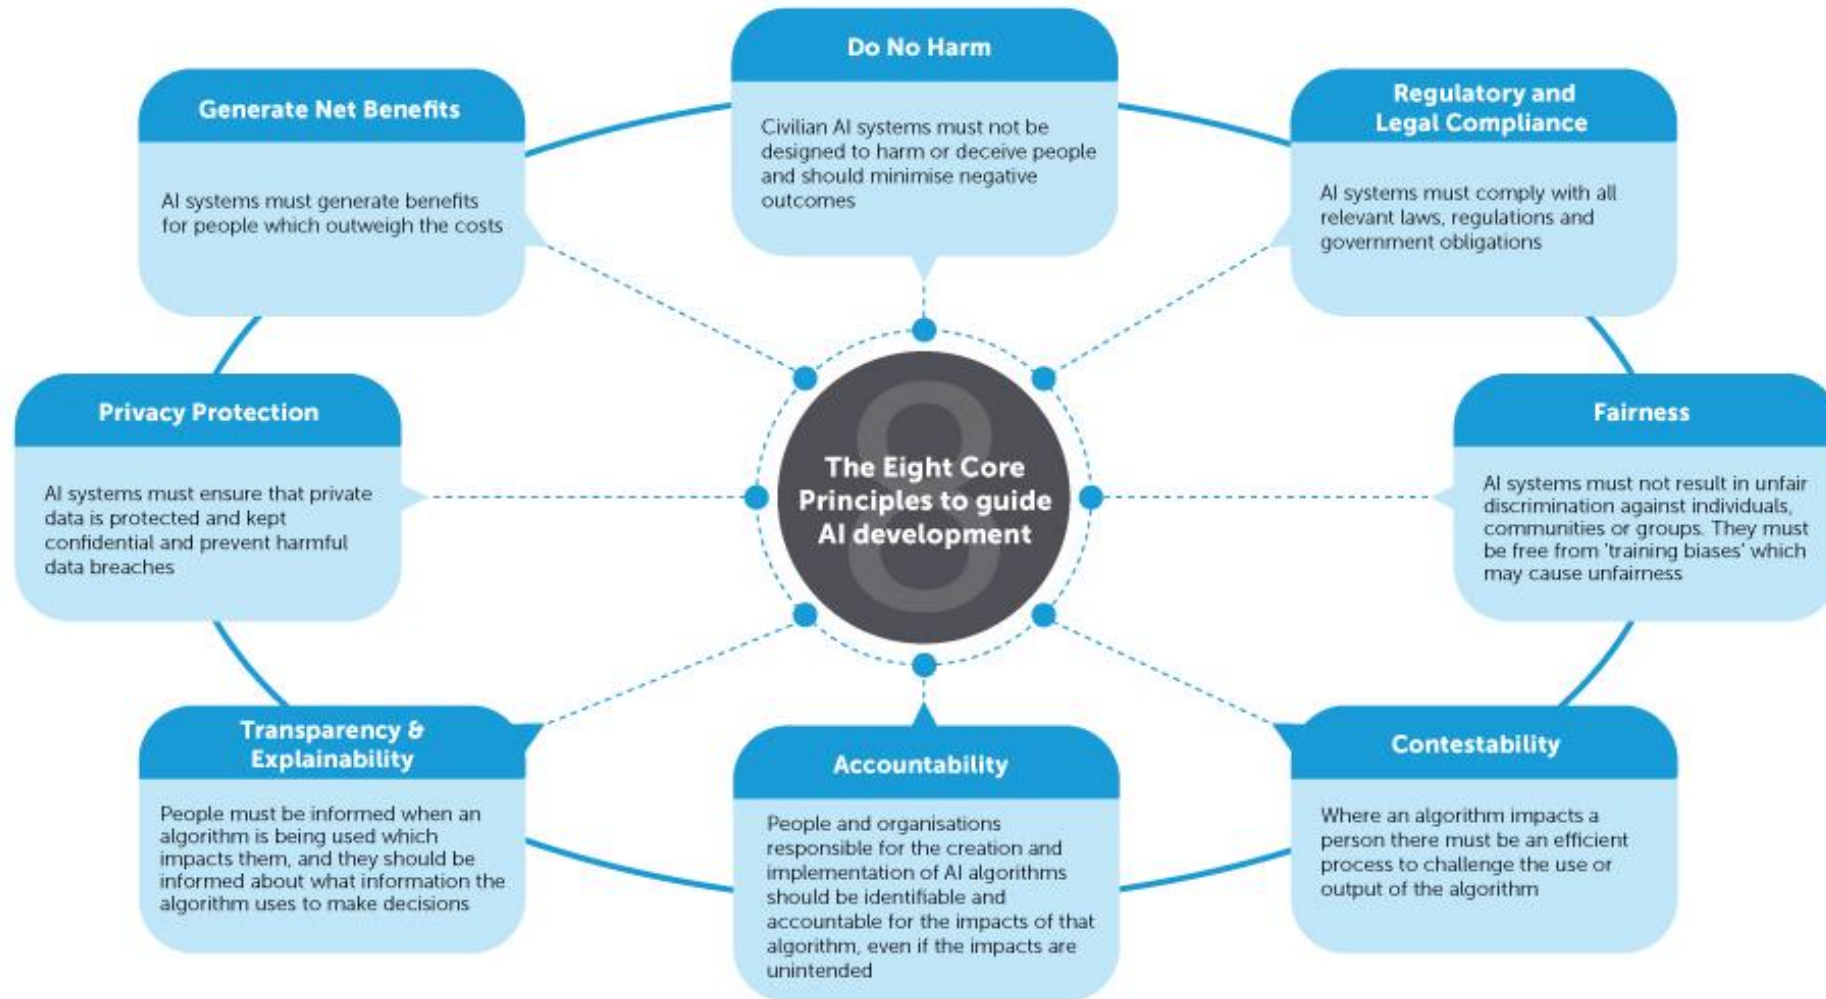

Further information on findings and methodology is available in *Principled Artificial Intelligence: Mapping Consensus in Ethical and Rights-Based Approaches* (Berkman Klein, 2020) available at [cyber.harvard.edu](http://cyber.harvard.edu).

# How do we inculcate responsibility in AI development for the future?

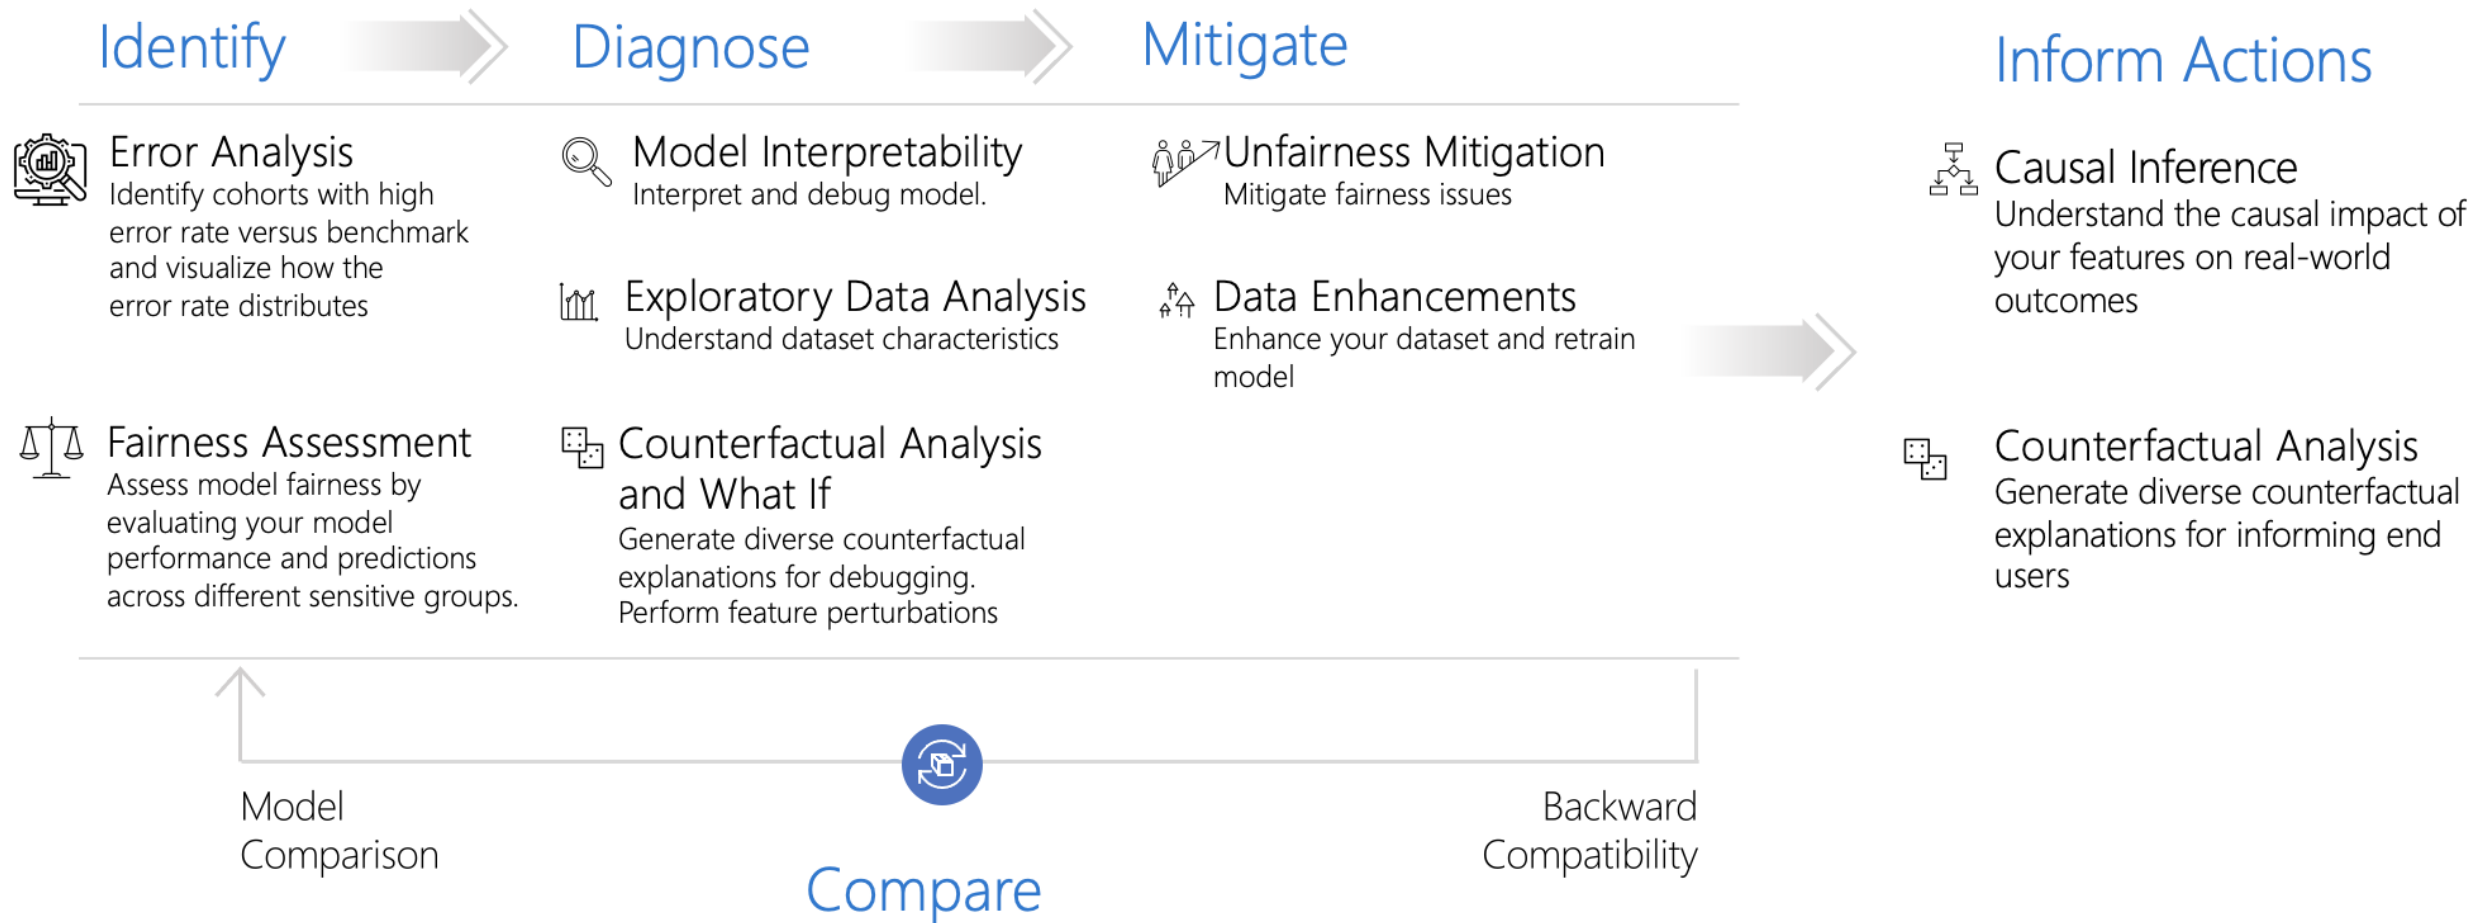

## Responsible AI in AI modelling

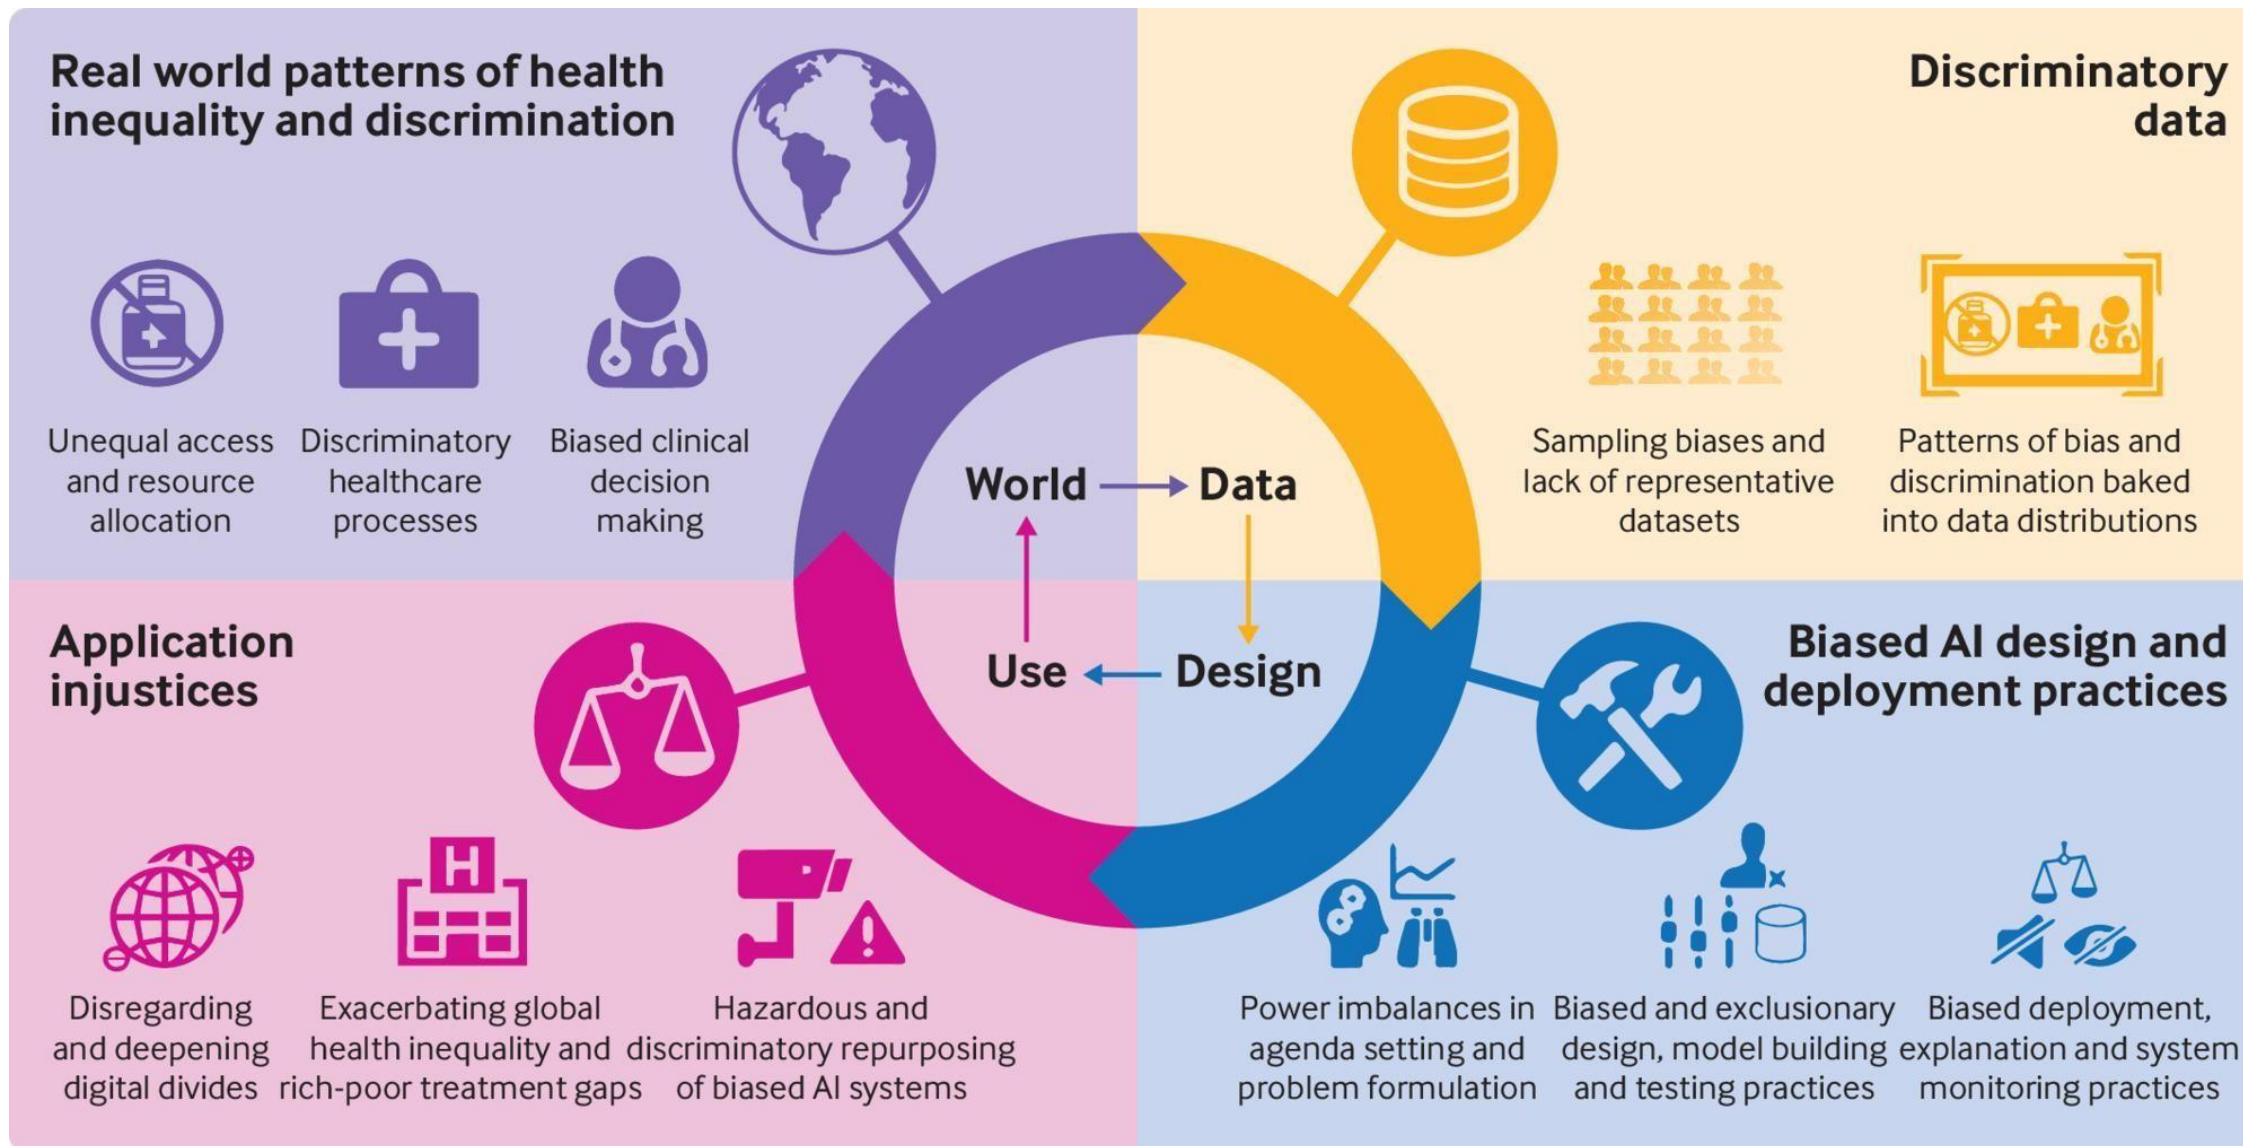

# What is the AI toolbox for responsible modelling?

# BIAS in AI- Focus on the healthcare industry as an example

# The future of AI

# Quantum computing

## THE ERA OF QUANTUM COMPUTING IS HERE

We are now reaching the fifth generation of computers

**1ST GENERATION**  
1940-1959  
VACUUM TUBES

**2ND GENERATION**  
1956-1964  
TRANSISTORS

**3RD GENERATION**  
1964-1971  
INTEGRATED CIRCUITS

**4TH GENERATION**  
1971-PRESENT  
MICROPROCESSORS

**5TH GENERATION**  
PRESENT AND BEYOND  
QUANTUM COMPUTERS

### Why quantum computing matters

Quantum computing will enable us to perform some computations that would take more time than the age of the universe to do on a classical computer

### Applications of quantum computing

BIG DATA ANALYTICS

DESIGNING BETTER DRUGS

MACHINE LEARNING

CRYPTOGRAPHY

### The three known types of quantum computing

#### 1 Quantum Annealer

DIFFICULTY LEVEL

The quantum annealer is least powerful and most restrictive form of quantum computers. It is the easiest to build, yet can only perform one specific function. The consensus of the scientific community is that a quantum annealer has no known advantages over conventional computing.

##### APPLICATION

■ Optimisation

##### GENERALITY

■ Restrictive

##### COMPUTATIONAL POWER

■ Same as traditional computers

#### 2 Analog Quantum

DIFFICULTY LEVEL

The analog quantum computer will be able to simulate complex quantum interactions that are intractable for any known conventional machine, or combinations of these machines. It is conjectured that the analog quantum computer will contain somewhere between 50 to 100 qubits.

##### APPLICATION

■ Quantum Chemistry

■ Material Science

■ Optimisation Problems

■ Sampling

■ Quantum Dynamics

##### GENERALITY

■ Partial

##### COMPUTATIONAL POWER

■ High

#### 3 Universal Quantum

DIFFICULTY LEVEL

The universal quantum computer is the most powerful, the most general, and the hardest to build, posing a number of difficult technical challenges. Current estimates indicate that this machine will comprise more than 100,000 physical qubits.

##### APPLICATION

■ Secure computing

■ Machine Learning

■ Cryptography

■ Quantum Chemistry

■ Material Science

■ Optimisation Problems

■ Sampling

■ Quantum Dynamics

■ Searching

##### GENERALITY

■ Complete with known speed up

##### COMPUTATIONAL POWER

■ Very high
